Supplementary table 1. Overview of earlier meta-analyses

First Author	Publication year	Search date	Population	Number of RCTs	Total N	Pooled effect	Conclusion
Jans <sup>35</sup>	2010	December 2009	Pregnant or post-partum, either depressed or non-depressed	7 (Llorente, Krauss-Etschmann, Rees, Freeman, Su, Mattes, Doornbos)	612	-0.03 (95%CI -0.18 to 0.13; P=.76)	The question of whether EPA and DHA administration is effective in the prevention or treatment of perinatal depression cannot be answered yet.
Dennis <sup>36</sup>	2013	January 2013	Pregnant with antenatal depression	2 (Freeman, Su)	55	NA	The evidence is inconclusive to allow us to make any recommendations for omega-3 fatty acids for the treatment of antenatal depression.
Miller <sup>37</sup>	2013	April 2013	Pregnant or given birth in the previous 6 wks, not taking antidepressants, not depressed	1 (Mozurkewich)	126	NA	There is insufficient evidence to conclude that DHA or EPA prevent postnatal depression.
Grosso <sup>38</sup>	2014	August 2013	Women with perinatal depression (including DSM- defined diagnosis of MDD and prevention of post-partum depression)	6 (Freeman, Su, Rees, Llorente, Doornbos, Mozurkewich)	Separate analyses for: Antenatal MDD (N=121)  Healthy pregnant women (N=403)	Antenatal MDD: 0.24 SD (95%CI -0.73 to 1.21; P=.63)  Healthy pregnant women: -0.05 SD (95%CI -0.24 to 0.15; P=.64)	Analyses led to inconclusive results.
Wei-Hong <sup>39</sup>	2017	April 2015	Pregnant women with MDD and receiving no other treatment than omega-3 fatty acids	4 (Freeman, Su, Rees, Kaviani)	201	0.75 (95%CI 0.47 to 1.04)	Omega-3 fatty acid supplementation resulted in better efficacy than placebo. Evidence is limited due to the small number of studies and participants.

van Ravesteyn <sup>6</sup>	2017	June 2016	Pregnant women with MDD or dysthymic disorder diagnosed during pregnancy using interview	3 (Freeman, Rees, Su)	81	$g = -0.51$ (95%CI -1.02 to -0.01; $P=.06$ )	The results of omega-3 fatty acids intake are mixed
Middleton <sup>40</sup>	2018	August 2018	Pregnant women, depressed or non-depressed	9 in total (Freeman, Kaviani, Mozurkewich, Rees, Su, Vaz, Carlson, Judge, Makrides)  Postnatal depression: 2 (Judge, Mozurkewich)	Postnatal depression n: 2431	Postnatal depression: average RR 0.99 (95%CI 0.56 to 1.77)	The effects of omega-3 supplementation on perinatal depression cannot be determined due to insufficient evidence.
Smith <sup>41</sup>	2019	March 2018	Pregnant women with depression during the antenatal period	3 (Freeman, Mozurkewich, Su)	172	$-0.12$ (95%CI $-0.76$ to $0.52$ ); $Z=.37$ ; $P=.71$	There is insufficient evidence for an effect of fish oil. This may be due to small sample sizes, heterogeneity, high risk of biases and too few studies.

**Supplementary table 2. Quality of the evidence of the overall and subgroup meta-analyses on the effect of omega-3 fatty acids for perinatal depression**

Subgroup	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Publication bias	Effect size	Final GRADE score
Overall	+4, RCTs	-1, other <sup>1</sup>	0 <sup>2</sup>	0	-1, imprecision	0, undetected	0	⊕⊕⊖⊖ low
Depressed	+4, RCTs	-1, other <sup>1</sup>	-1, heterogeneity	0	-1, imprecision	0, undetected	0	⊕⊖⊖⊖ very low
Non-depressed	+4, RCTs	-1, other <sup>1</sup>	0, no heterogeneity	0	0	0, undetected	0	⊕⊕⊕⊖ moderate
Pregnant	+4, RCTs	-1, other <sup>1</sup>	0, no heterogeneity	0	0	0, undetected	0	⊕⊕⊕⊖ moderate
Postpartum	+4, RCTs	-1, other <sup>1</sup>	-1, heterogeneity	0	-1, imprecision	0, undetected	0	⊕⊖⊖⊖ very low
Postpartum depressed	+4, RCTs	-1, other <sup>1</sup>	-1, heterogeneity	0	-1, imprecision	0, undetected	0	⊕⊖⊖⊖ very low

<sup>1</sup> Several potential biases remained unclear, e.g. due to the lack of a pre-published protocol.

<sup>2</sup> Heterogeneity explained by differences in populations

## Supplementary figure 2. Depressed and postpartum

Forest plot showing the meta-analysis effects of included randomized controlled trials on omega-3 fatty acid supplementation vs. placebo for postpartum depression.

### Supplementary figure 3. Funnel plot

The funnel plot showed no clear asymmetry, apart from one positive outlier with a medium sample size (20). Classic and Orwin's fail-safe N's were 65 and 18, respectively. This means that 65 studies must have been missed to bring the P-value to insignificance for the fixed effects main analysis, and 18 studies without an effect must have been missed to bring the effect size to  $<0.1$  SDM. Regarding the Begg and Mazumbar rank-correlation test, Kendall's tau's with and without continuity correction were  $-0.26$  ( $P_{2\text{-sided}}=0.13$ ), and  $-0.27$  ( $P_{2\text{-sided}}=0.12$ ), respectively, indicative of no publication bias. Egger's regression intercept was  $-0.82$  ( $95\%CI=-2.99$  to  $1.35$ ;  $P_{2\text{-sided}}=0.44$ ), also suggesting no significant publication bias. Duval and Tweedie's trim-and-fill method using random or fixed effects model suggested that no studies were missed to the right of the mean (i.e. that would reduce the overall effect for omega-3 PUFAs vs. placebo).
